UTC UNISONIC TECHNOLOGIES CO., LTD

UPS604

LINEAR INTEGRATED CIRCUIT

HIGH PERFORMANCE CURRENT MODE POWER SWITCH

DESCRIPTION

The UTC **UPS604** is designed to provide several special enhancements to satisfy the needs, for example, Power-Saving mode for low standby power (<0.3W), Frequency Hopping, Constant Output Power Limiting, Slope Compensation, Over Current Protection (OCP), Over Voltage Protection (OVP), Over Load Protection (OLP), Under Voltage Lock Out (UVLO), Short Circuit Protection (SCP), Over Temperature Protection (OTP) etc. IC will be shutdown or can auto-restart in situations.

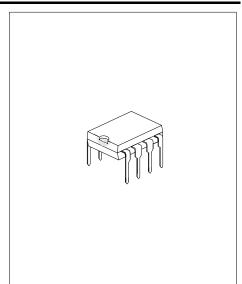

FEATURE

- * Low startup current (about 22µA)
- * Fixed switching frequency(Norm. is 68KHz)
- * Frequency hopping for Improved EMI Performance.
- * Lower than 0.3W Standby Power Design
- * Linearly decreasing frequency to 26KHz during light load
- * Soft start
- * Internal Slope Compensation
- * Constant Power Limiting for universal AC input Range
- * Gate Output Maximum Voltage Clamp(15V)
- * Max duty cycle 74%
- * Over temperature protection
- * Overload protection
- * Over voltage protection
- * Leading edge blanking
- * Cycle-by-Cycle current limiting
- * Under Voltage Lock Out
- * Short Circuit Protection

ORDERING INFORMATION

■ PIN CONFIGURATION

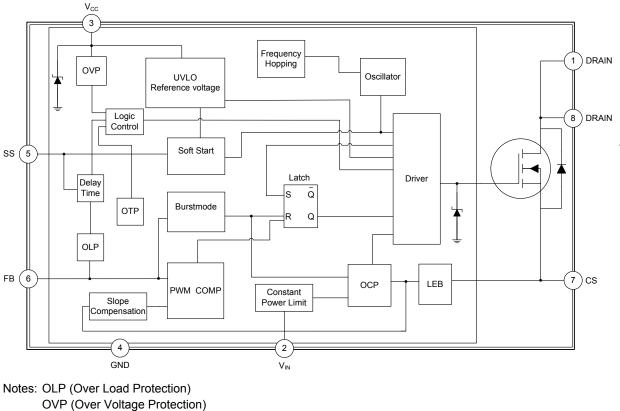

PIN DESCRIPTION

PIN	NAME	FUNCTION
1	DRAIN	Power MOSFET drain
2	V _{IN}	For startup and constant power limit, this pin is pulled to the line input via resistor
3	V _{CC}	Supply voltage
4	GND	Ground
5	SS	Soft-start
6	FB	Feedback
7	CS	Controller current sense input
8	DRAIN	Power MOSFET drain

BLOCK DIAGRAM

Notes: OLP (Over Load Protection) OVP (Over Voltage Protection) OTP (Over Temperature Protection) OCP (Over Current Protection) UVLO (Under Voltage Latch-Out) LEB (Led Edge Blanking) SS (Soft Start)

■ ABSOLUTE MAXIMUM RATINGS (Ta=25°C, unless otherwise specified)

PARAMETER	SYMBOL	RATINGS	UNIT
Supply Voltage	Vcc	30	V
Input Voltage to Vin Pin	Vin	30	V
Input Voltage to FB Pin	V _{FB}	-0.3 ~ 6.2	V
Input Voltage to CS Pin	Vcs	-0.3 ~ 2.8	V
Junction Temperature	TJ	+150	°C
Operating Temperature	T _{OPR}	-40 ~ +125	°C
Storage Temperature	T _{STG}	-50 ~ +150	°C

Note: Absolute maximum ratings are those values beyond which the device could be permanently damaged. Absolute maximum ratings are stress ratings only and functional device operation is not implied.

OPERATING RANGE

PARAMETER	SYMBOL	RATINGS	UNIT
Supply Voltage	V _{CC}	8.6 ~ 22	V

■ ELECTRICAL CHARACTERISTICS (Ta=25°C, V_{CC}=15V, unless otherwise specified)

PARAMETER	SYMBOL	TEST CONDITIONS	MIN	TYP	MAX	UNIT
SUPPLY SECTION						
Start Up Current	I _{STR}	$V_{CC} = V_{CC(ON)} - 0.1V$		22	45	μA

Notes: 1. Pulse Test: Pulse width≤300µs, Duty cycle≤2%

2. Essentially independent of operating temperature

FUNCTIONAL DESCRIPTION

The internal reference voltages and bias circuit work at V_{CC} > V_{THD (ON)}, and shutdown at V_{CC} < V_{CC (MIN)}.

(1) Soft-Start

When every IC power on, driver output duty cycle will be decided by voltage V_{SS} on soft-start capacitor and V_{CS} on current sense resistor at beginning. After V_{SS} reach 4.2V, the whole soft-start phase end, and driver duty cycle depend on V_{FB} and V_{CS}. The relation among V_{SS}, V_{FB} and V_{OUT} as followed FIG.3.

Furthermore, soft-start phase should end before V_{CC} reach $V_{CC (MIN)}$ during V_{CC} power on. Otherwise, if soft-start phase remain not end before V_{CC} reach $V_{CC (MIN)}$ during V_{CC} power on, IC will enter auto-restart phase and not set up V_{OUT} . So the value of C_{SS} should be between 0.1µFand 4.7µF.

Finally soft-start also set OVP1 active phase. OVP1 active phase between 0 and $V_{SS(DEACT)}$, OVP1 will not be sensed after V_{SS} reach $V_{SS(DEACT)}$. The Soft-start phase T_{SS} : T_{SS} = 23.8×C_{SS} (ms) (Example: C_{SS}=0.47µF, then T_{SS} =23.8×0.47=11.2ms).

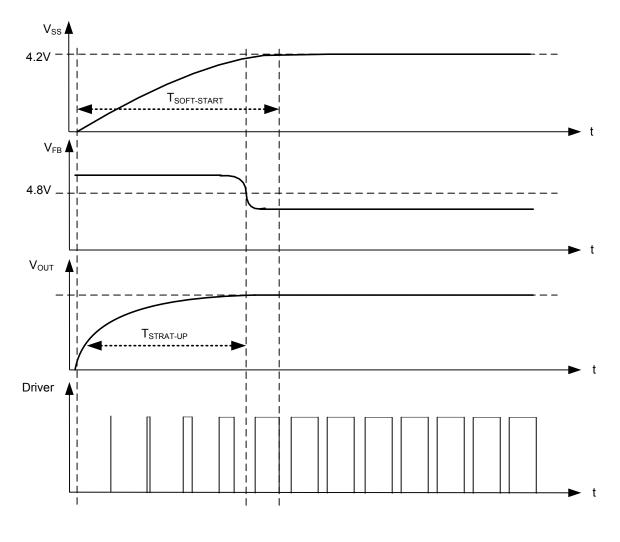

Fig.3 Soft-start phase

FUNCTIONAL DESCRIPTION(Cont.)

(2) Switch Frequency Set

The maximum switch frequency is set to 68kHz. Switch frequency is modulated by output power P_{OUT} during IC operating. At no load or light load condition, most of the power dissipation in a switching mode power supply is from switching loss on the MOSFET transistor, the core loss of the transformer and the loss on the subber circuit. The magnitude of power loss is in proportion to the number of switching events within a fixed period of time. So lower switch frequency at lower load, which more and more improve IC's efficiency at light load. At from no load to light load condition, The IC will operate at from Burst mode to Reducing Frequency Mode. The relation curve between f_{SW} and P_{OUT}/P_{OUT} (MAX) as followed FIG.4.

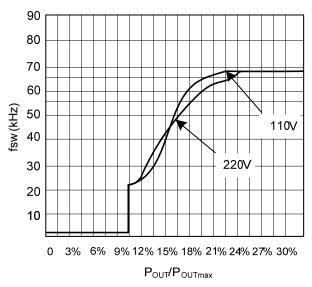

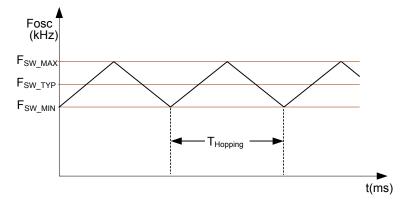

FIG.4 The relation curve between f_{SW} and relative output power $P_{OUT}/$ $P_{OUT\,(MAX)}$

(3) Internal Synchronized Slope Compensation

Built-in slope compensation circuit adds voltage ramp onto the current sense input voltage for PWM generation, this greatly improves the close loop stability at CCM and prevents the sub-harmonic oscillation and thus reduces the output ripple voltage.

(4) Frequency Hopping For EMI Improvement

The Frequency hopping is implemented in the IC; there are two oscillators built-in the IC. The first oscillator is to set the normal switching frequency; the switching frequency is modulated with a period signal generated by the 2nd oscillator. The relation between the first oscillator and the 2nd oscillator as followed FIG.5. So the tone energy is evenly spread out, the spread spectrum minimizes the conduction band EMI and therefore eases the system design in meeting stringent EMI requirement.

FUNCTIONAL DESCRIPTION(Cont.)

(5) Constant Output Power Limit

When the SENSE voltage, across the sense resistor R_S , reaches the threshold voltage, around 0.8V, the output GATE drive will be turned off after a small propagation delay t_D . This propagation delay will introduce an additional current proportional to $t_P \times V_{IN}/L_P$. Since the propagation delay is nearly constant regardless of the input line voltage V_{IN} . Higher input line voltage will result in a larger additional current and hence the output power limit is also higher than that under low input line voltage. To compensate this variation for wide AC input range, the threshold voltage is adjusted by the V_{IN} current. Since V_{IN} pin is connected to the rectified input line voltage through a resistor R_{VIN} , a higher line voltage will generate higher V_{IN} current into the V_{IN} pin. The threshold voltage is decreased if the V_{IN} current is increased. Smaller threshold voltage, forces the output GATE drive to terminate earlier, thus reduce the total PWM turn-on time and make the output power equal to that of low line input. This proprietary internal compensation ensures a constant output power limit for wide AC input voltage from 90VAC to 264VAC.

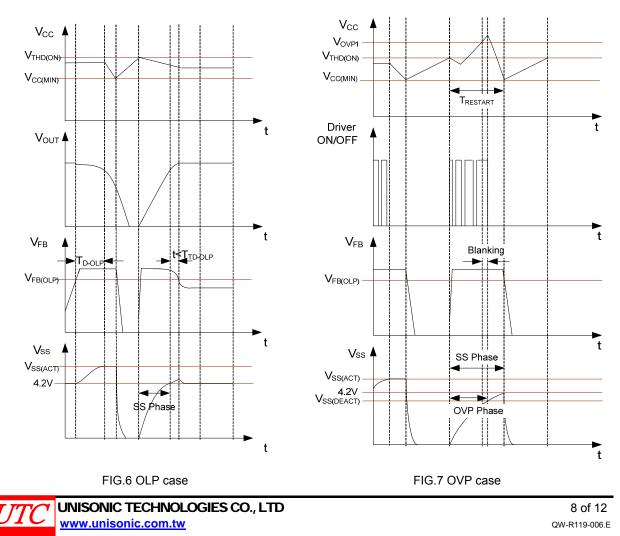

(6) Protection section

The IC takes on more protection functions such as OLP, OVP and OTP etc. In case of those failure modes for continual blanking time, the driver is shut down. At the same time, IC enters auto-restart, V_{CC} power on and driver is reset after V_{CC} power on again.

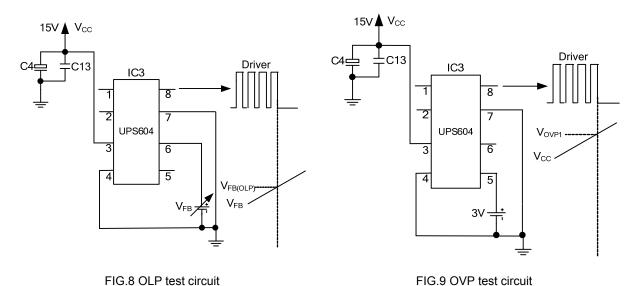

OLP

After soft-start phase end, IC will shutdown driver if over load state occurs for continual T_{D-OLP} . OLP function will not inactive during soft-start phase. OLP case as followed FIG. 6. The test circuit as followed FIG.8. T_{D-OLP} =5.53× T_{SS} . **OVP**

There are two kinds of OVP circuits, the first OVP function are enabled only when $V_{SS} < V_{SS (DEACT)} & V_{FB} > V_{FB}$ (OLP) during soft-start phase. During above condition, driver will be shutdown if over voltage state occurs ($V_{CC} > V_{OVP1}$) for continual a blanking time. The first OVP function will not inactive after soft-start phase. The second OVP will shutdown the switching of the power MOSFET whenever $V_{CC} > V_{OVP2}$. The first OVP case as followed FIG.7. The test circuit as followed FIG.9.

■ FUNCTIONAL DESCRIPTION(Cont.)

ОТР

OTP will shut down driver when junction temperature $T_J > T_{(THR)}$ for continual a blanking time.

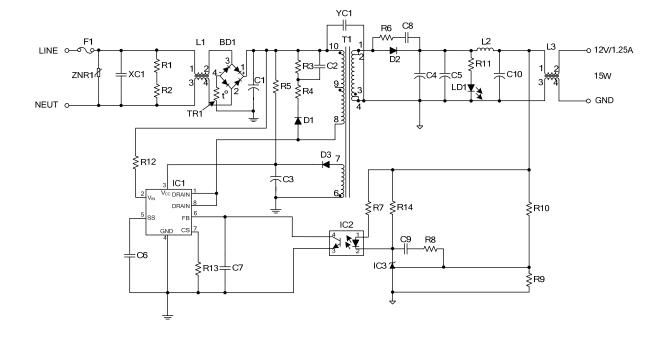

(7) Driver Output Section

The driver-stage drives the gate of the MOSFET and is optimized to minimize EMI and to provide high circuit efficiency. This is done by reducing the switch on slope when reaching the MOSFET threshold. This is achieved by a slope control of the rising edge at the driver's output. The output driver is clamped by an internal 15V Zener diode in order to protect power MOSFET transistors against undesirable gate over voltage.

(8) Inside power switch MOS transistor

Specific power MOS transistor parameter is as "POWER MOS TRANSISTOR SECTION" in electrical characteristics table.
